Bad Design

Relational Schema Design

Goal of relational schema design is to avoid **anomalies** and **redundancy**.

- Update anomaly: one occurrence of a fact is changed, but not all occurrences
- · Insertion anomaly: related facts are required when a tuple is inserted
- Deletion anomaly: valid fact is lost when a tuple is deleted

Example of Bad Design

Drinkers(name, addr, beersLiked, brewery, favBeer)

name	addr	beersLiked	brewery	favBeer
Alice	Nantes	Trompe Souris	La Divatte	Titan
Alice	???	Titan	Bouffay	???
Bob	Rennes	Titan	???	Titan

Data is redundant, because each of the ???'s can be figured out by using the FD's name \rightarrow addr favBeer and beersLiked \rightarrow brewery

4

Bad Design: Update Anomalies

name	addr	beersLiked	brewery	favBeer
Alice	Nantes Vannes	Trompe Souris	La Divatte Bouffay	Titan
Alice	Nantes	Titan	Bouffay	Titan
Bob	Rennes	Titan	Bouffay	Titan

• If Alice moves to Vannes, will we remember to change each of her tuples?

.

Bad Design: Deletion Anomalies

name	addr	beersLiked	brewery	favBeer
Alice	Nantes	Trompe Souris	La Divatte	Titan
Alice	Nantes	Titan	Bouffay	Titan
Bob	Rennes	Titan	Bouffay	Titan

• If nobody likes Trompe Souris anymore, we lose track of the fact that La Divatte brews Trompe Souris

Bad Design: Insertion Anomalies

name	addr	beersLiked	brewery	favBeer
Alice	Nantes	Trompe Souris	La Divatte	Titan
Alice	Nantes	Titan	Bouffay	Titan
Bob	Rennes	Titan	Bouffay	Titan
Charlie	Nantes	Mistral	Aerofab	Mistral

• If Charlie comes into play, one must know beers s/he likes and their breweries, otherwise null values

(

BCNF

Boyce-Codd Normal Form

Definition (BCNF)

We say a relation R is in BCNF if whenever $X \to Y$ is a nontrivial FD that holds in R, X is a superkey

- Remember: **nontrivial** means Y is not contained in X
- Remember: a superkey is any superset of a key (not necessarily a proper superset)

8

Example: BCNF

Drinkers(name, addr, beersLiked, brewery, favBeer)

- · FD's:
 - name \rightarrow addr favBeer
 - beersLiked → brewery
- Only key is {name, beersLiked}
- In each FD, the left-hand side is not a superkey
- Any one of these FD's shows **Drinkers** is not in BCNF

Another Example

Beers(name, brewery, brewAddr)

- FD's:
 - name \rightarrow brewery
 - brewery → brewAddr
- Only key is {name}
- \cdot name \rightarrow brewery does not violate BCNF, but brewery \rightarrow brewAddr does

9

Decomposition into BCNF

Given: relation R with FD's \mathcal{F}

- 1. Look among the given FD's for a BCNF violation $X \to Y$
 - If any FD following from ${\cal F}$ violates BCNF, then there will surely be an FD in ${\cal F}$ itself that violates BCNF
- 2. Compute X^+
 - Not all attributes, or else X is a superkey

 $\overline{\text{Decompose } R \text{ Using } X} \to Y$

3. Replace R by relations with schemas:

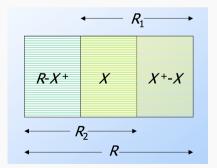

•
$$R_1 = X^+$$

•
$$R_2 = R - (X^+ - X) = \overline{X^+} \cup X$$

4. Project given FD's ${\mathcal F}$ onto the two new relations

12

Decomposition Picture

J. Ullman

13

Example: BCNF Decomposition

Drinkers(name, addr, beersLiked, brewery, favBeer)

 $\mathcal{F} = \{\text{name} \rightarrow \text{addr, name} \rightarrow \text{favBeer, beersLiked} \rightarrow \text{brewery}\}$

- 1. Pick BCNF violation name→ addr
- 2. Close the left-hand side: {name}+ = {name, addr, favBeer}
- 3. Decomposed relations:
 - Drinkers1(name, addr, favBeer)
 - · Drinkers2(<u>name</u>, <u>beersLiked</u>, brewery)

Example (cont'd)

We are not done; we need to check Drinkers1 and Drinkers2 for BCNF

- Projecting FD's is easy here
- For Drinkers1(<u>name</u>, addr, favBeer), relevant FD's are name→ addr
 and name→ favBeer
- Thus, {name} is the only key and Drinkers1 is in BCNF

15

Example (cont'd)

- For Drinkers2(<u>name</u>, <u>beersLiked</u>, brewery), the only FD is beersLiked → brewery, and the only key is {name, beersLiked}
- Violation of BCNF
- beersLiked⁺ = {beersLiked, brewery}, so we decompose **Drinkers2** into:
 - · Drinkers3(<u>beersLiked</u>, brewery)
 - Drinkers4(name, beersLiked)

16

${\sf Example-Concluded}$

The resulting decomposition of Drinkers

- Drinkers1(<u>name</u>, addr, favBeer)
- · Drinkers3(<u>beersLiked</u>, brewery)
- Drinkers4(name, beersLiked)

Notice: Drinkers1 tells us about drinkers, Drinkers3 tells us about beers, and Drinkers4 tells us the relationship between drinkers and the beers they like

3NF

Third Normal Form — Motivation

There is one structure of FD's that causes trouble when we decompose

- AB \rightarrow C and C \rightarrow B
 - Example: A = street address, B = city, C = zip code
- There are two keys, {A,B} and {A,C}
- \cdot C \rightarrow B is a BCNF violation, so we must decompose into AC, BC

We Cannot Enforce FD's

The problem is that if we use AC and BC as our database schema, we cannot enforce the FD $AB \rightarrow C$ by checking FD's in these decomposed relations

A = street, B = city, and C = zip

	street	zip
R =	50 Otages	44000
	50 Otages	44100

$$S = egin{array}{c|c} zip & city \\ 44000 & Nantes \\ 44100 & Nantes \\ \end{array}$$

 $\{\text{street, zip}\}\ \text{is key in }R,\{\text{zip}\}\ \text{is key in }S$

An Unenforceable FD

	street	city	zip
$R\bowtie S$ =	50 Otages	Nantes	44000
	50 Otages	Nantes	44100

 $R\bowtie S$ joins tuples with equal zip codes

Although no FD's were violated in the decomposed relations, FD street city \rightarrow zip is violated by the database as a whole

• 3rd Normal Form (3NF) modifies the BCNF condition so we do not have to decompose in this problem situation

3rd Normal Form

Definition (3NF (C. Zaniolo, 1982¹))

Every FD $X \to A$ satisfies one of those three conditions:

- 1. $X \rightarrow A$ is trivial
- 2. X is a superkey
- 3. A is prime

(more flexible than BCNF)

• An attribute is prime if it is a member of any key

In other words, a nontrivial FD $X \to A$ violates 3NF if and only if X is not a superkey, or A is not prime

2

¹Equivalent to (E.F. Codd, 1971).

Example: 3NF

- In our problem situation with FD's AB \rightarrow C and C \rightarrow B, we have keys AB and AC
- · A, B and C are each prime
- Although $C \rightarrow B$ violates BCNF, it does not violate 3NF (B is prime)
- · One can decide not to decompose to BCNF, still being 3NF

22

3NF and BCNF (cont'd)

- · We can get (1) with a BCNF decomposition
- We can get both (1) and (2) with a 3NF decomposition
- But we can't always get (1) and (2) with a BCNF decomposition
 - · street-city-zip is an example

What 3NF and BCNF Give You?

Two important properties of a decomposition

- 1. **Lossless Join**: it should be possible to project the original relations onto the decomposed schema, and then reconstruct the original
- 2. **Dependency Preservation**: it should be possible to check in the projected relations whether all the given FD's are satisfied

- 7

Testing for a Lossless Join

- If we project R onto R_1 , R_2 , ..., R_n , can we recover R by rejoining?
 - A projected fragment: $R_i = \pi_{X_i}(R)$
 - Does R equal to $R_1 \bowtie R_2 \bowtie \ldots \bowtie R_n$?
- \cdot Any tuple in R can be recovered from its projected fragments
 - $R \subseteq R_1 \bowtie R_2 \bowtie \ldots \bowtie R_n$ is obvious
- So the only question is: when we rejoin, do we ever get back something we didn't have originally?
 - $R \supseteq R_1 \bowtie R_2 \bowtie \ldots \bowtie R_n$ must be proved

The Chase Test

- Suppose tuple *t* comes back in the join
- Then t is the join of projections of some tuples of R, one for each R_i of the decomposition
- \cdot Can we use the given FD's to show that one of these tuples must be t?

26

Example: The Chase

- · Let R(A, B, C, D) and the decomposition be $R_1(A, B)$, $R_2(B, C)$ and $R_3(C, D)$
- Let the given FD's be $\mathcal{F} = \{C \to D, B \to A\}$
- \cdot Suppose the tuple t=abcd is the join of tuples projected onto AB, BC, CD

The Chase – (cont'd)

Procedure

- 1. Start by assuming t = abc...
- 2. For each i, there is a tuple s_i of R that has a, b, c, ... in the attributes of R_i
- 3. s_i can have any values in other attributes
- 4. We'll use the same letter as in t, but with a subscript, for these components

27

The Tableau

Let's build an instance of R from tuple t=abcd in $\pi_{AB}(R)\bowtie\pi_{BC}(R)\bowtie\pi_{CD}(R)$

R	А	В	C	D
from AB part of t	a	b	c_1	d_1
from BC part of t	a 2 a	b	c	$\frac{d}{d} d$
from CD part of t	a_3	b_3	c	d

- Use $B \rightarrow A$ to state a_2 must be a
- Use $C \rightarrow D$ to state d_2 must be d

We've proved the second tuple must be t=abcd; then $(\pi_{AB}(R)\bowtie\pi_{BC}(R)\bowtie\pi_{CD}(R))\subseteq R!$

Summary of the Chase

Build the Tableau, then

- 1. If two rows agree in the left side of a FD, make their right sides agree too
- 2. Always replace a subscripted symbol by the corresponding unsubscripted one, if possible
- 3. If we ever get an unsubscripted row, we know any tuple in the project-join is in the original table (the join is lossless)
- 4. Otherwise, the final tableau is a counterexample

Example: Lossy Join

- Same relation R(A, B, C, D) and same decomposition AB, BC, CD
- But with only the FD $C \rightarrow D$

31

The Tableau

• Use $C \rightarrow D$ to state d_2 must be d_1 and that's all

These three tuples are an example of *R* that shows **the join is lossy**:

 \cdot abcd is not in R, but we can project and rejoin to get t=abcd

$$t_1[AB] \bowtie t_2[BC] \bowtie t_3[CD] = abcd$$

3NF Decomposition

There is always a lossless-join and dependency-preserving 3NF decomposition

How to achieve 3NF?

- 1. Perform the iterative binary decomposition process up to 3NF only
- 2. Use the **3NF Synthesis**
 - · Need a minimal basis for the FD's

3

Minimal Cover and 3NF Synthesis

Minimal Cover

also known as minimal basis or even canonical cover

A set of FD's is a minimal cover iff

- 1. rhs's are single attributes
- 2. No redundant FD, ie FD that can be discarded
- 3. No extraneous attribute in lhs, ie that can be removed from the lhs

4

Constructing a Minimal Cover

Given a set of FD's ${\cal F}$

Finding a minimal cover \mathcal{F}_{\min} requires:

- 1. Split rhs's
- 2. Repeatedly try to remove an FD X \rightarrow A and see if the remaining FD's are equivalent to the original
- 3. Repeatedly try to remove an attribute B from a lhs BX \rightarrow A and see if the resulting FD's are equivalent to the original
- 4. Iterate 2-3 up to stable

Constructing a Minimal Cover — for Real

How to achieve Step 2: $\mathcal{F} - \{X \to A\} \equiv \mathcal{F}$?

$$\Leftrightarrow \mathcal{F} - \{X \to A\} \models X \to A$$
? (to prove $\mathcal{F} - \{X \to A\}$ implies \mathcal{F})

$$\Leftrightarrow$$
 Check for $A \in X^+$ wrt $\mathcal{F} - \{X \to A\}$

How to achieve Step 3: $(\mathcal{F} - \{BX \to A\} \cup \{X \to A\}) \equiv \mathcal{F}$?

$$\Leftrightarrow \mathcal{F} \text{ implies } (\mathcal{F} - \{BX \to A\} \cup \{X \to A\})$$

• The other way round is obvious since $X \to A \models BX \to A$

$$\Leftrightarrow \mathcal{F} \models X \to A$$

 \Leftrightarrow Check for $A \in X^+$ wrt \mathcal{F}

Example: Minimal Cover

Given the FD's $\mathcal{F} = \{ABC \rightarrow CD, A \rightarrow B, C \rightarrow A\}$

- Step 1: $\mathcal{F}_1 = \{ABC \rightarrow C, ABC \rightarrow D, A \rightarrow B, C \rightarrow A\}$
- · Step2:
 - remove (trivial) $ABC \rightarrow C$ to get $\mathcal{F}_2 = \mathcal{F}_1 \{ABC \rightarrow C\}$
 - cannot remove $ABC \to D$, since $D \notin ABC^+_{\mathcal{F}_2 \{ABC \to D\}} = ABC$

 - cannot remove $A \to B$, since $B \not\in A^+_{\mathcal{F}_2 \{A \to B\}} = A$ cannot remove $C \to A$, since $A \not\in C^+_{\mathcal{F}_2 \{C \to A\}} = C$

37

Example: Minimal Cover (cont'd)

Given the FD's $\mathcal{F} = \{ABC \rightarrow CD, A \rightarrow B, C \rightarrow A\}$

Step 1-2 yields to $\mathcal{F}_2 = \{ABC \to D, A \to B, C \to A\}$

- Step 3:
 - remove A in $ABC \to D$ since $D \in BC_{\mathcal{F}_2}^+ = BCAD$. Define \mathcal{F}_3
 - remove B in $BC \to D$ since $D \in C_{\mathcal{F}_0}^+ = CABD$. Define \mathcal{F}_4
 - cannot remove C in $C \to D$ (singleton in lhs)
 - nothing to do for $A \to B$ and $C \to A$ (singletons in *lhs*)

Finally, $\mathcal{F}_{\min} = \mathcal{F}_4 = \{C \to D, A \to B, C \to A\}$

Properties of Minimal Cover

Given a set of FD's \mathcal{F}

- FD's in \mathcal{F}_{\min} are irreducibles
- $\mathcal{F}_{\min} \equiv \mathcal{F}$ that is equivalent to $\mathcal{F}_{\min}^+ = \mathcal{F}^+$
- \mathcal{F}_{\min} is not unique
 - · depends on the nondeterministic choices in Steps 2-3
- \cdot \mathcal{F}_{\min} is required for the 3NF synthetis algorithm

3NF Synthesis

- 1. Create one relation for each *lhs* of FD's in the minimal cover
 - · Schema is the union of *lhs* and set of *rhs*'s
- 2. Discard relation R(X) if S(XY) exists
- 3. If no key is contained in an FD, then add one relation whose schema is some key

Example: 3NF Synthesis

Relation R(A, B, C, D, E) with FD's $\mathcal{F} = \{AB \to C, AB \to D, C \to B, E \to B\}$

Assume \mathcal{F} is a minimal cover

Decomposition

- 1. ABCD, CB and EB
- 2. Then, remove CB since $CB \subseteq ABCD$
- 3. And add AE for a key

41

Example: 3NF Synthesis (cont'd)

Resulting decomposition is $R_1(ABCD)$, $R_2(EB)$ and $R_3(AE)$

- R_1 R_2 and R_3 are 3NF
- R_1 is not BCNF by $C \rightarrow B$

4

Why It Works?

3NF Synthesis

- **Preserves dependencies**: each FD from a minimal cover is contained in a relation, thus preserved
- Lossless Join: use the chase to show that the row for the relation that contains a key can be made all unsubscripted variables
- 3NF: hard part, a property of minimal covers

The Many Other Normal Forms

First Normal Form

The very baseline of Relational Database Design

1NF

Relation has (a) a **key** and (b) **atomic** columns and (c) **no repeating groups** of columns

- · Sets or tuples or tables are not allowed as attribute values
- (beersLiked₁, beersLiked₂, BeersLiked₃) is not allowed as a subset of columns

44

Second Normal Form

2NF

1NF and every non-prime attribute is **fully** functionally dependent on keys

- · Remind: non-prime attributes are not key attributes
- FD $X \rightarrow A$ is full iff A doesn't depend on a proper subset of X
- 2NF is not so relevant in DB design

45

Example: 2NF

Drinkers(name, addr, beersLiked, brewery, favBeer)

FD's are name \rightarrow addr favBeer and beersLiked \rightarrow brewery

- Drinkers is 1NF: (a) key, (b) atomic values (c) non-repeating attributes
- Drinkers is not 2NF
 - name beersLiked \rightarrow addr is not full, since name \rightarrow addr holds
- · Drinkers cannot be 3NF either

Normal Forms: Best Practices

1NF < 2NF < 3NF < BCNF

- · Always try to decompose up to BCNF
- · When one cannot get dependency preserving BCNF, may decide to stop to 3NF
- Denormalize below 3NF only for good reason (performance) or data model ${\rm shift^2}$

²nested relations, document db, key-value stores, ...

More Stringent Normal Forms

Beyond Functional Dependencies

- · Multi-Valued Dependencies: 4NF
- FD + Join Dependencies: ETNF (H. Darwen et al., 2012)
- JD: 5NF, 6NF
- · Domain and Key constraints: DKNF

• ...

· But we still ignore the multivalued dependencies...

MVD's

MVD's are full constraints on relation³

Definition (Multi-Valued Dependency)

Let R be a relation of schema $\{X, Y, Z\}$; $X \rightarrow Y$ holds whenever (x, y, z) and (x, t, u) both belong to R, it implies that (x, y, u) and (x, t, z) should also be in R

Informally

 $X \rightarrow Y$ holds if for any value of X, there exists a well-defined set of values of Y and a well-defined set of values of Z, independant one with the other.

MVD's (cont'd)

$$A \twoheadrightarrow B \mid C$$

Α	В	С
a_1	b_1	c_1
a_1	b_1	c_2
a_1	b_2	c_1
a_1	b_2	c_2
a_2	b_1	c_1
a_2	b_1	c_3

MVD's from Physics:

- Department {Building} {Employee {Telephone}}
- · MVD's = {Dpt → Bding | Emp, Tel; Dpt, Emp → Tel | Bding}

Properties of MVD's

Inference System [FoD 1994, Theorem 8.3.5 p. 172]

Let U a given set of attributes and X, Y, Z are subsets of U;

- · Complementation: if $X \rightarrow Y$, then $X \rightarrow (U Y)$
- Reflexivity: if $Y \subseteq X$, then $X \rightarrow Y$ (trivial)
- Augmentation: if $X \rightarrow Y$, then $XZ \rightarrow YZ$
- Transitivity: if X woheadrightarrow Y and Y woheadrightarrow Z then X woheadrightarrow (Z Y)
- Conversion: if $X \to Y$, then $X \twoheadrightarrow Y$
- Interaction: if $X \twoheadrightarrow Y$ and $XY \to Z$, then $X \to (Z Y)$

Armstrong's Axioms (both on FD's and MVD's) constitute a sound and complete inference system for the FD+MVD closure computation

³All the attributes are necessarily involved.

4th Normal Form

Definition (4NF)

For every non trivial MVD $X \rightarrow Y$ in R, then X is a superkey

Straightforward extension of BCNF to MVD's.

Losseless-join decomposition of R(X, Y, Z)

Decomposition (X, Y) and (X, Z) is losseless-join iff $X \rightarrow Y$ holds in R

Pros & Cons

- · 3NF/BCNF design
 - must have
 - best trade-off between redondancy vs. decomposition
 - · a priori BCNF, except on dependency loss, then design choice
- 4NF design
 - requires many joins in queries (performance pitfall)
 - · and loses the big picture of class book entities
- 1NF relational view
 - eliminates the need for users/apps to perform deadly joins
 - but loses the one-to-one mapping between tuples and objects
 - has a large amount of redundancy
 - · and could yield to insertion, deletion, update anomalies

5
